Radiometer calibration overview

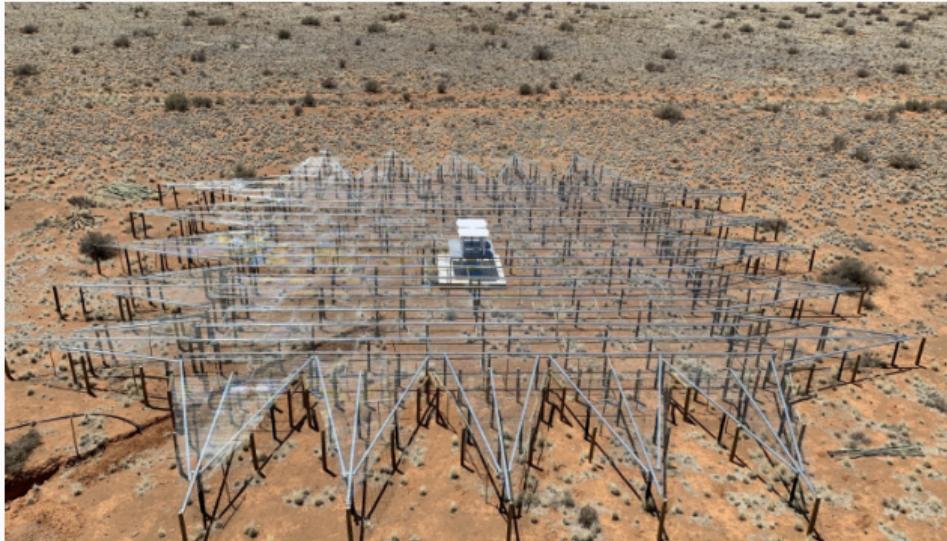

What is calibration?

How to calibrate?

Why is calibration in Global 21cm Cosmology difficult?

We measure *sky averaged* signal.

Antenna LNA impedance mismatch

Very faint signal.

How to calibrate (in a bit more detail...)?

Objective: Map input temperature to output power.

Key Factors:

- LNA introduces time-dependent gain, $g(t)$.
- Impedance mismatch adds noise (T_{rec}) to the system.

Link Output Power to Input Temperature:

$$P_{\text{out}}^{\text{src}} = gM \times (T_{\text{in}}^{\text{src}} + T_{\text{rec}}) \quad (1)$$

$$M = \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{(1 - |\Gamma_{\text{cal}}|^2)} | \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_{\text{cal}} \Gamma_{\text{rec}}} |^2$$

Note: All parameters above are frequency-dependent, but the notation has been simplified here and thereafter for convenience.

Receiver/source mismatch

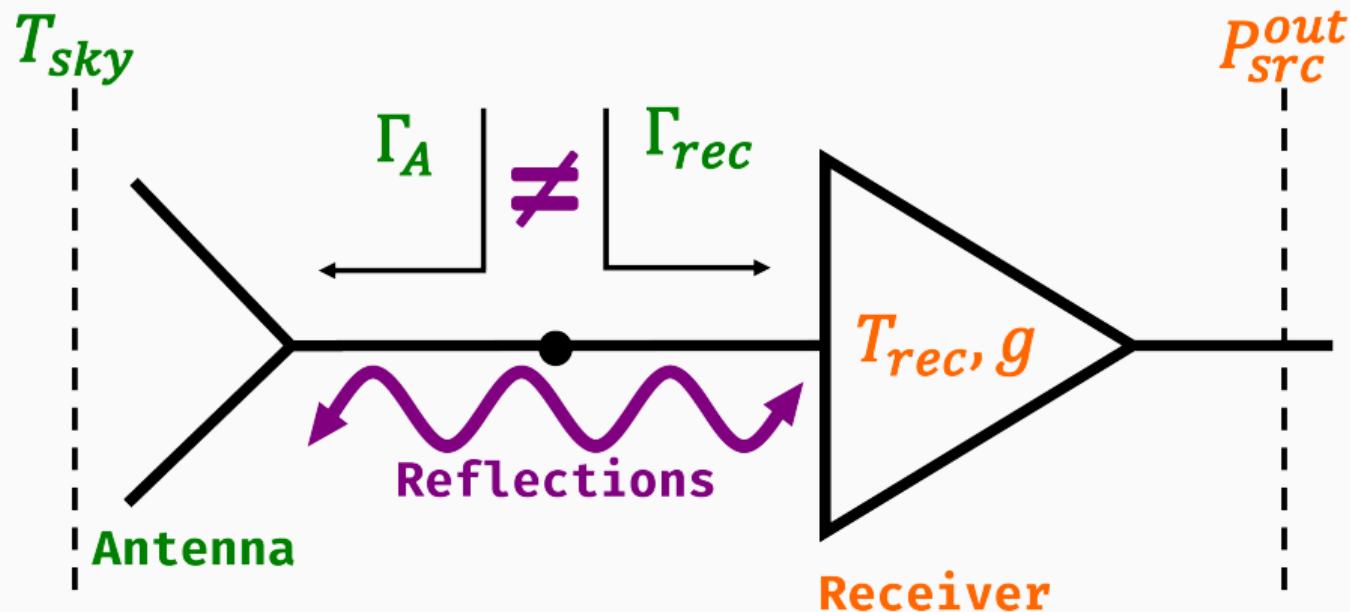

Figure 1: Schematic of the receiver system showing the signal path from antenna to digitizer

Dealing with reflections...

$$P_{\text{out}}^{\text{src}} = gM (T_{\text{in}}^{\text{src}} + T_{\text{rec}}) \quad (2)$$

Noise Parameter Equation:

$$P_{\text{out}}^{\text{src}} = gM \left(T_{\text{in}}^{\text{src}} + T_{\text{min}} + T_0 \frac{4R_N}{Z_0} \frac{|\Gamma_{\text{src}} - \Gamma_{\text{opt}}|^2}{(1 - |\Gamma_{\text{src}}|^2)(1 + |\Gamma_{\text{opt}}|^2)} \right) \quad (3)$$

Noise Wave Equation:

$$\begin{aligned} P_{\text{out}}^{\text{src}} = & g \left[T_0 + T_{\text{unc}} |\Gamma_s|^2 \left| \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right|^2 \right. \\ & + T_s (1 - |\Gamma_s|^2) \left| \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right|^2 + T_{\cos} \Re \left(\Gamma_s \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) \\ & \left. + T_{\sin} \Im \left(\Gamma_s \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) \right] \quad (4) \end{aligned}$$

- g - Gain
- T_{min} - Minimum Noise Temperature
- R_N - Noise Resistance
- Γ_{opt} - Optimum Reflection Coefficient
- Γ_s - Source Reflection Coefficient
- Γ_{rec} - Receiver Reflection Coefficient
- T_s - Source Temperature
- $P_{\text{out}}^{\text{src}}$ - Power out
- $T_{\text{unc}}, \cos, \sin$ - Noise wave parameters
- T_0 reference temperature

Radiometer calibration with machine learning

ML calibration overview

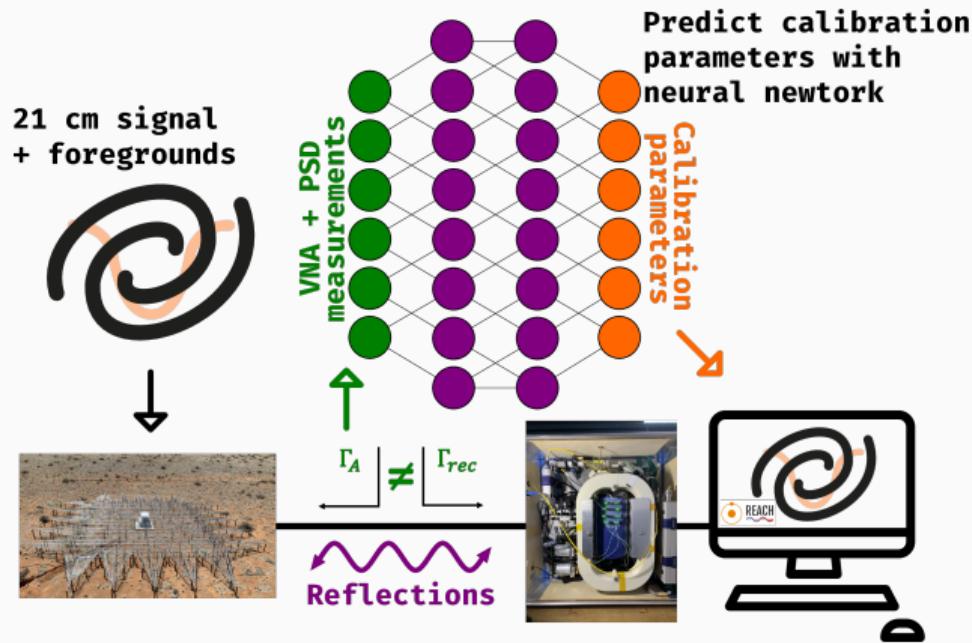

Figure 2: High-level overview of the machine learning-based calibration framework

Machine learning calibration steps

1. Define the Loss Function

Regress over measured power and predicted power.

$$\mathcal{L} = \frac{1}{n} \sum_{i=1}^n (\mathcal{P}_{\text{measured},i} - \mathcal{P}_{\text{pred},i})^2 \quad (5)$$

2. Write Down the Equation for $\mathcal{P}_{\text{pred}}$

Using the noise wave formalism, relate $\mathcal{P}_{\text{pred}}$ to T_{src} .

$$\begin{aligned} \mathcal{P}_{\text{pred}} &= \mathbf{g} \cdot M(T_{\text{in}}^{\text{src}} \\ &+ T_{\text{min}} + T_0 \frac{4R_N}{Z_0} \frac{|\Gamma_{\text{src}} - \Gamma_{\text{opt}}|^2}{(1 - |\Gamma_{\text{src}}|^2)(1 + |\Gamma_{\text{opt}}|^2)} \Big) \end{aligned} \quad (6)$$

3. Minimise the Loss Function

$$\theta^* = \arg \min_{\theta} \mathcal{L}(\theta) \quad (7)$$

parameter vector θ includes all tunable parameters in the model:

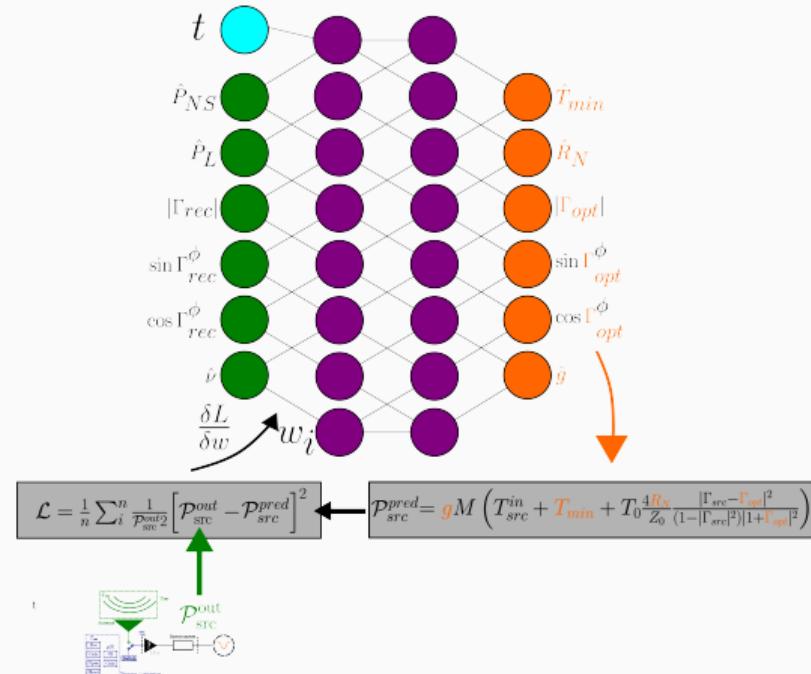

$$\theta = \{\mathbf{g}, T_{\text{min}}, R_N, \Gamma_{\text{opt}}^\phi, |\Gamma_{\text{opt}}|\} \quad (8)$$

4. Rearrange and Predict (T_{src}) using θ^*

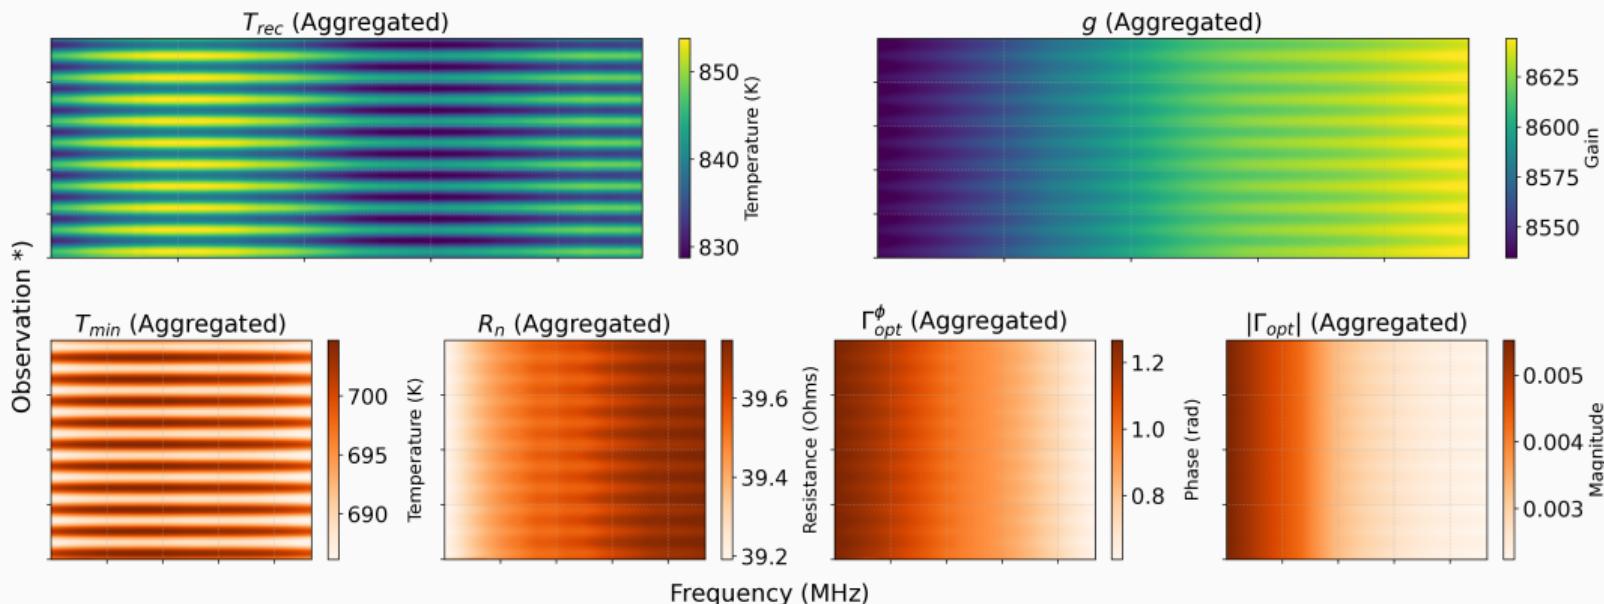

$$\begin{aligned} T_{\text{src}} &= \frac{\mathcal{P}_{\text{pred}}}{\mathbf{g}^* \cdot M} \\ &- \left(T_{\text{min}}^* + T_0 \frac{4R_N^*}{Z_0} \frac{|\Gamma_{\text{src}} - \Gamma_{\text{opt}}^*|^2}{(1 - |\Gamma_{\text{src}}|^2)(1 + |\Gamma_{\text{opt}}^*|^2)} \right) \end{aligned} \quad (9)$$

Learning non-linear time-dependent system drift

Neural Network Time Evolution

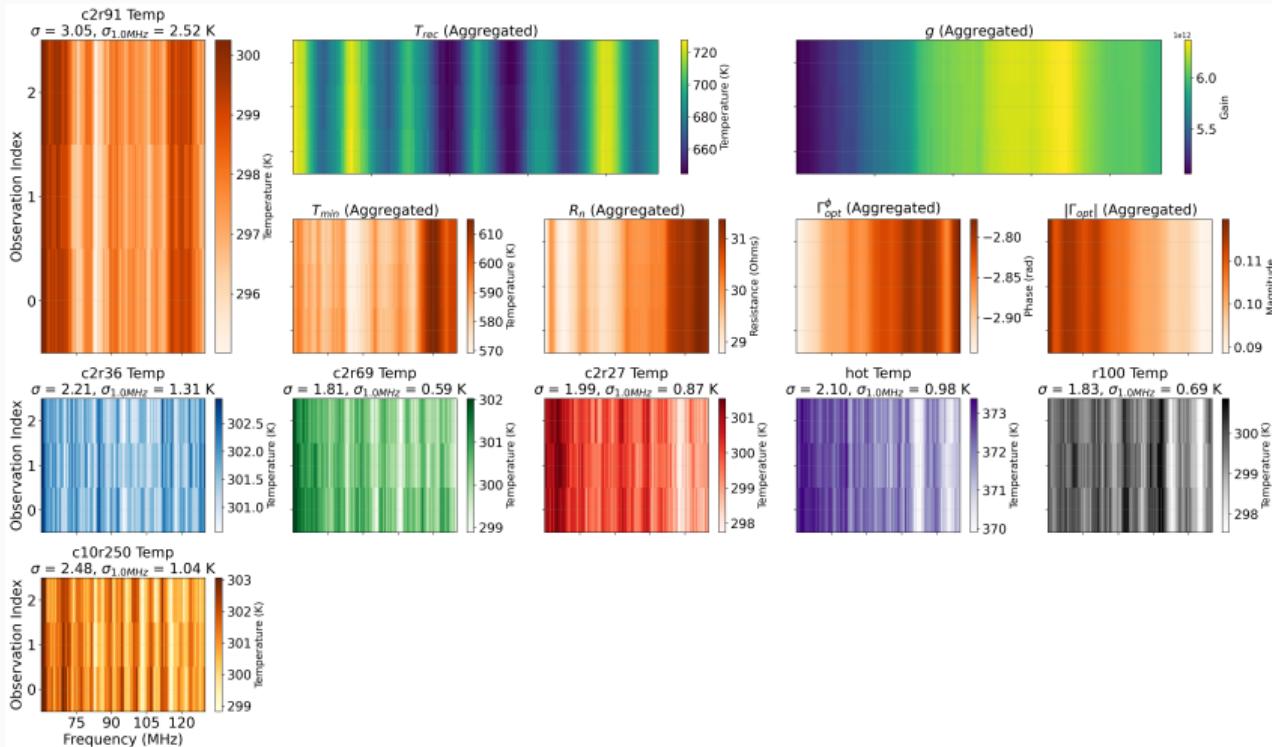

Inject system drift

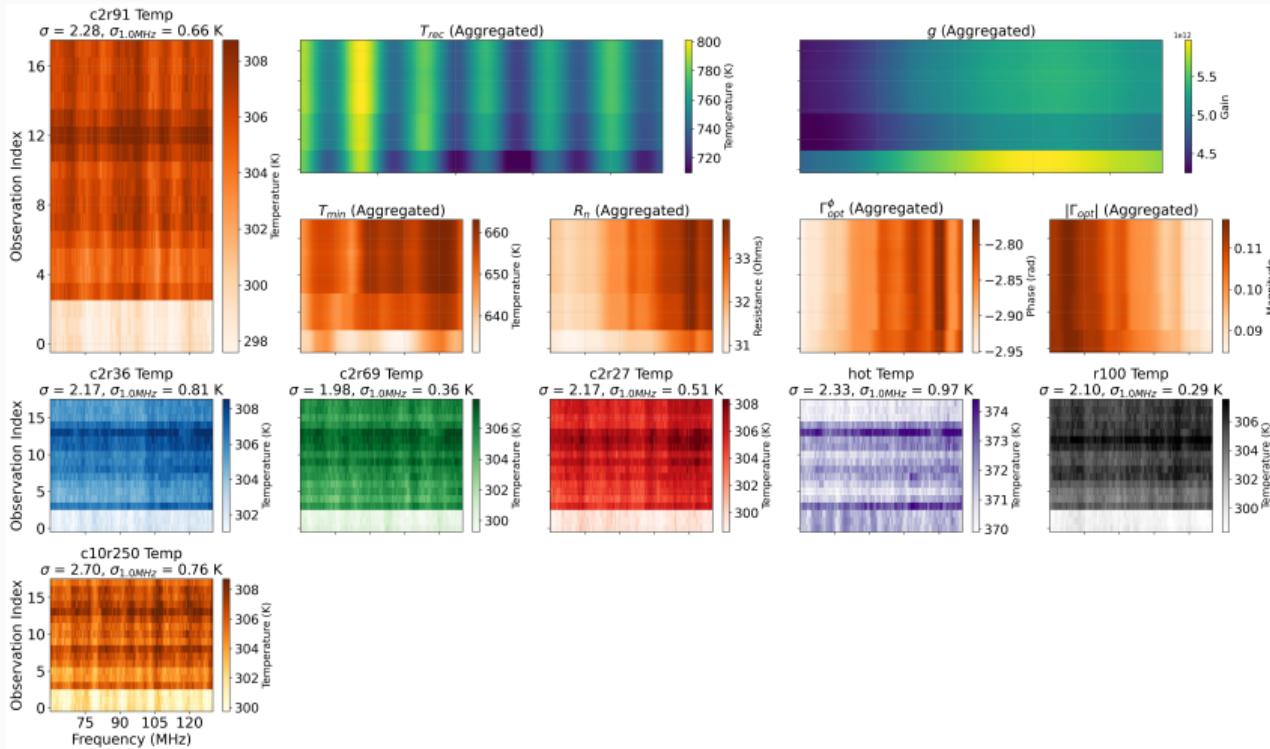

Inject a time varying sinusoid into T_{min} and predict the noise parameters → the network recovers this 'system drift'

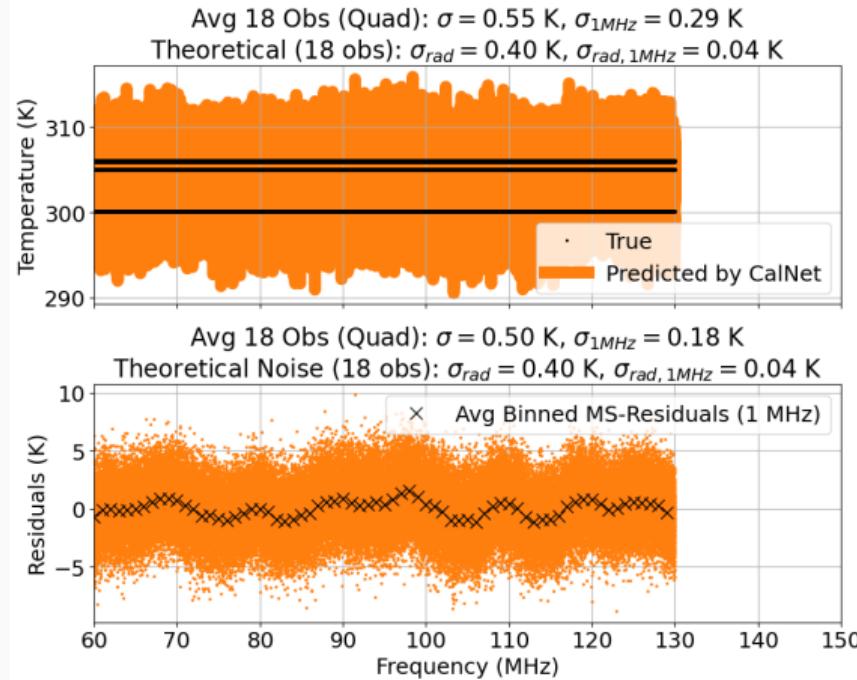

Single night, many observations

Many nights, many observations

Calibration Performance

- Significant improvement when combining many nights
- Calibration down to 0.18K
- Getting close to theoretical noise

Radiometers are crucial instruments in radio astronomy, forming the primary component of nearly all radio telescopes. They measure the intensity of electromagnetic radiation, converting this radiation into electrical signals. A radiometer's primary components are an antenna and a Low Noise Amplifier (LNA), which is the core of the "receiver" chain. Instrumental effects introduced by the receiver are typically corrected or removed during calibration. However, impedance mismatches between the antenna and receiver can introduce unwanted signal reflections and distortions. Traditional calibration methods, such as Dicke switching, alternate the receiver input between the antenna and a well-characterised reference source to mitigate errors by comparison. Recent advances in Machine Learning (ML) offer promising alternatives. Neural networks, which are trained using known signal sources, provide a powerful means to model and calibrate complex systems where traditional analytical approaches struggle. These methods are especially relevant for detecting the faint sky-averaged 21-cm signal from atomic hydrogen at high redshifts. This is one of the main challenges in observational Cosmology today. Here, for the first time, we introduce and test a machine learning-based calibration framework capable of achieving the precision required for radiometric experiments aiming to detect the 21-cm line.

Neural corrections

Neural LSQ residual diagnostics

Neural pre-corrected LSQ pipeline

1. Neural network predicts additive corrections: $\Delta T = \text{NN}(f, \Gamma)$.
2. Apply the correction to the measured spectrum: $T_{\text{corrected}} = T_{\text{measured}} + \Delta T$.
3. Run a least-squares solve inside the loss: $\theta = \arg \min_{\theta} \|X\theta - T_{\text{corrected}}\|^2$.
4. Predict the calibrated temperature: $T_{\text{pred}} = X\theta$.
5. Define the loss: $\mathcal{L} = \|T_{\text{pred}} - T_{\text{corrected}}\|^2$.

The LSQ solver is executed *inside* the training loop, so JAX backpropagates through the closed-form solve.

Neural pre-corrected LSQ mathematics

The LSQ design matrix for frequency f and calibrator c is

$$X_c = \begin{bmatrix} x_u & x_c & x_s & x_{NS} & x_L \end{bmatrix},$$

where the noise-wave formulation provides X from the calibrator and receiver S_{11} .

For each frequency we solve

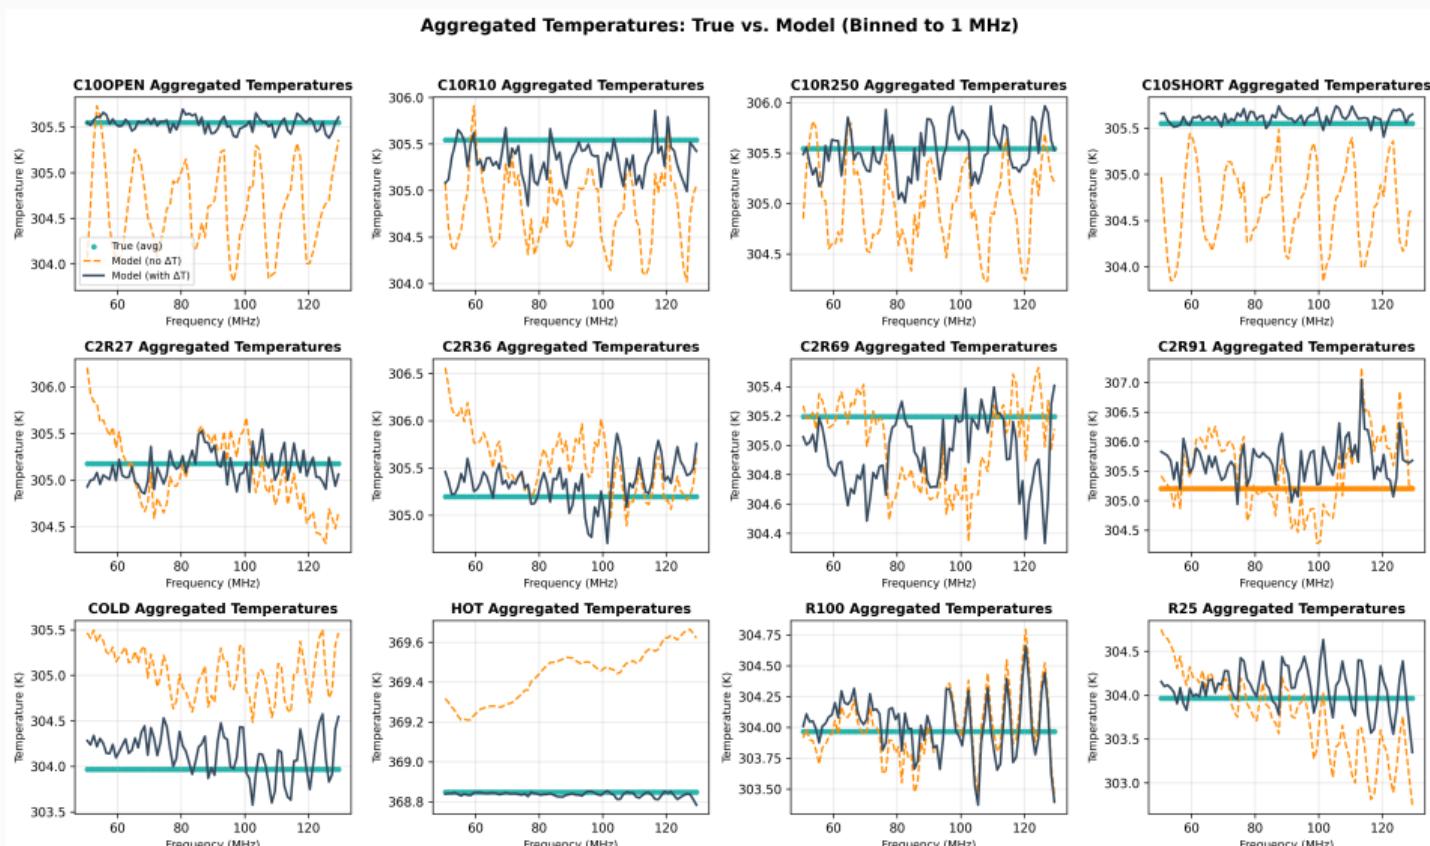

$$\theta(f) = \arg \min_{\theta} \|X(f)\theta - (T_{\text{measured}} + \text{NN}(f, \Gamma; w))\|^2,$$

and the training loss becomes

$$\mathcal{L}(w) = \sum_{f,c} [T_{\text{measured}}(c) - (X_c(f) \cdot \theta(f) - \text{NN}(f, \Gamma_c; w))]^2.$$

Optimising w therefore yields the neural correction weights that minimise the residual between corrected measurements and LSQ predictions.

Aggregated calibrator temperatures

Neural anomaly detection

Bayesian anomaly detection problem

- Each data point carries an anomaly mask $\varepsilon_i \in \{0, 1\}$ with Bernoulli prior $P(\varepsilon_i) = p_i^{\varepsilon_i} (1 - p_i)^{1 - \varepsilon_i}$.
- Likelihood blends the normal model $\mathcal{L}_i(\theta)$ and a uniform anomaly floor $\frac{1}{\Delta}$:

$$P(\mathcal{D}, \vec{\varepsilon} | \theta) = \prod_{i=1}^N [\mathcal{L}_i(\theta)(1 - p_i)]^{1 - \varepsilon_i} \left[\frac{p_i}{\Delta} \right]^{\varepsilon_i}.$$

- Dominant mask approximation yields the rule $\log \mathcal{L}_i + \log \Delta \leq \text{logit}(p_i)$ for deciding whether a point is anomalous.

Hard vs. soft mixture models

Hard mixture:

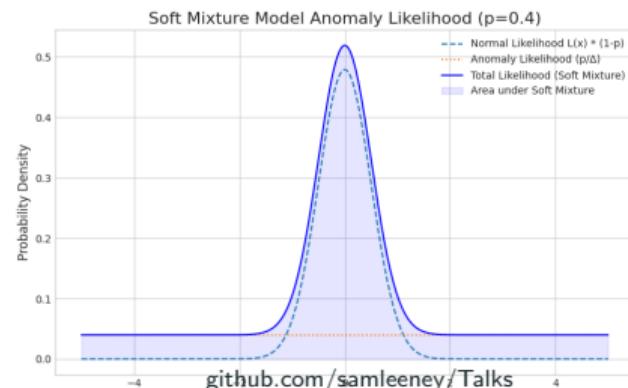

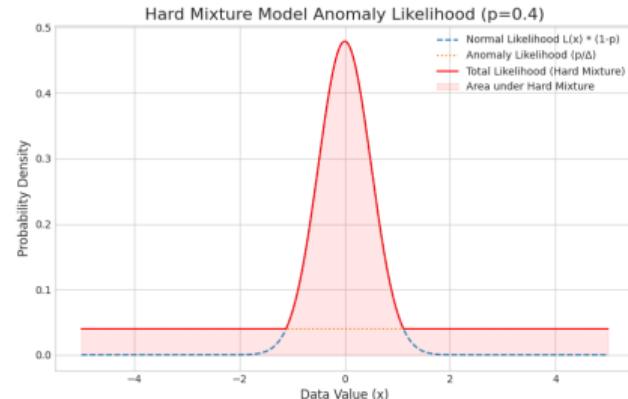

$$\log P(\mathcal{D}|\theta) = \sum_i \max \{ \log \mathcal{L}_i + \log(1 - p_i), \log p_i - \log \Delta \}$$

- Fast but clips between hypotheses.
- Sensitive when p_i varies with environment.

Soft mixture:

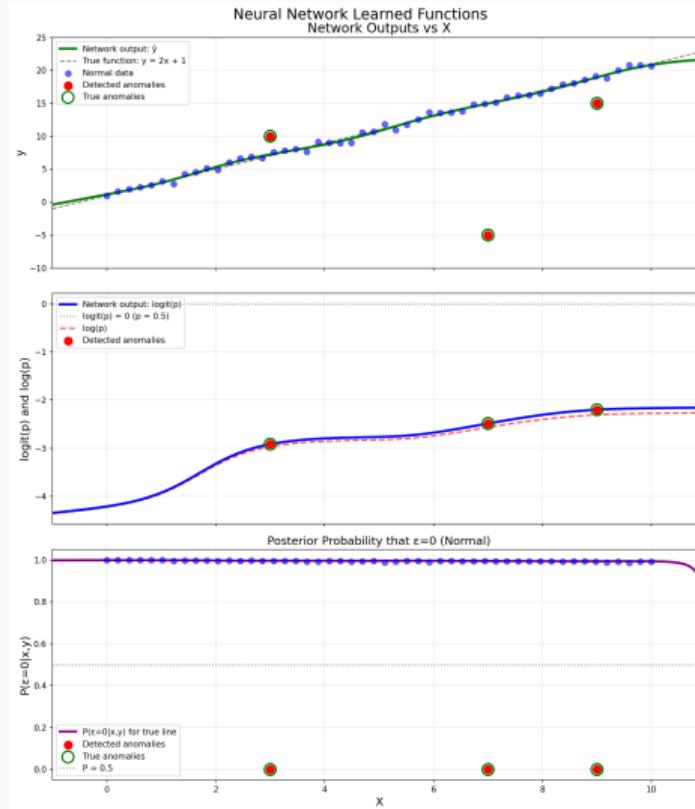

$$\log P(\mathcal{D}|\theta) = \sum_i \log \left[(1 - p_i) \mathcal{L}_i + \frac{p_i}{\Delta} \right]$$

- Smoothly marginalises corruption states.
- Posterior anomaly probability drops below 0.5 when $(1 - p_i) \mathcal{L}_i < \frac{p_i}{\Delta}$.

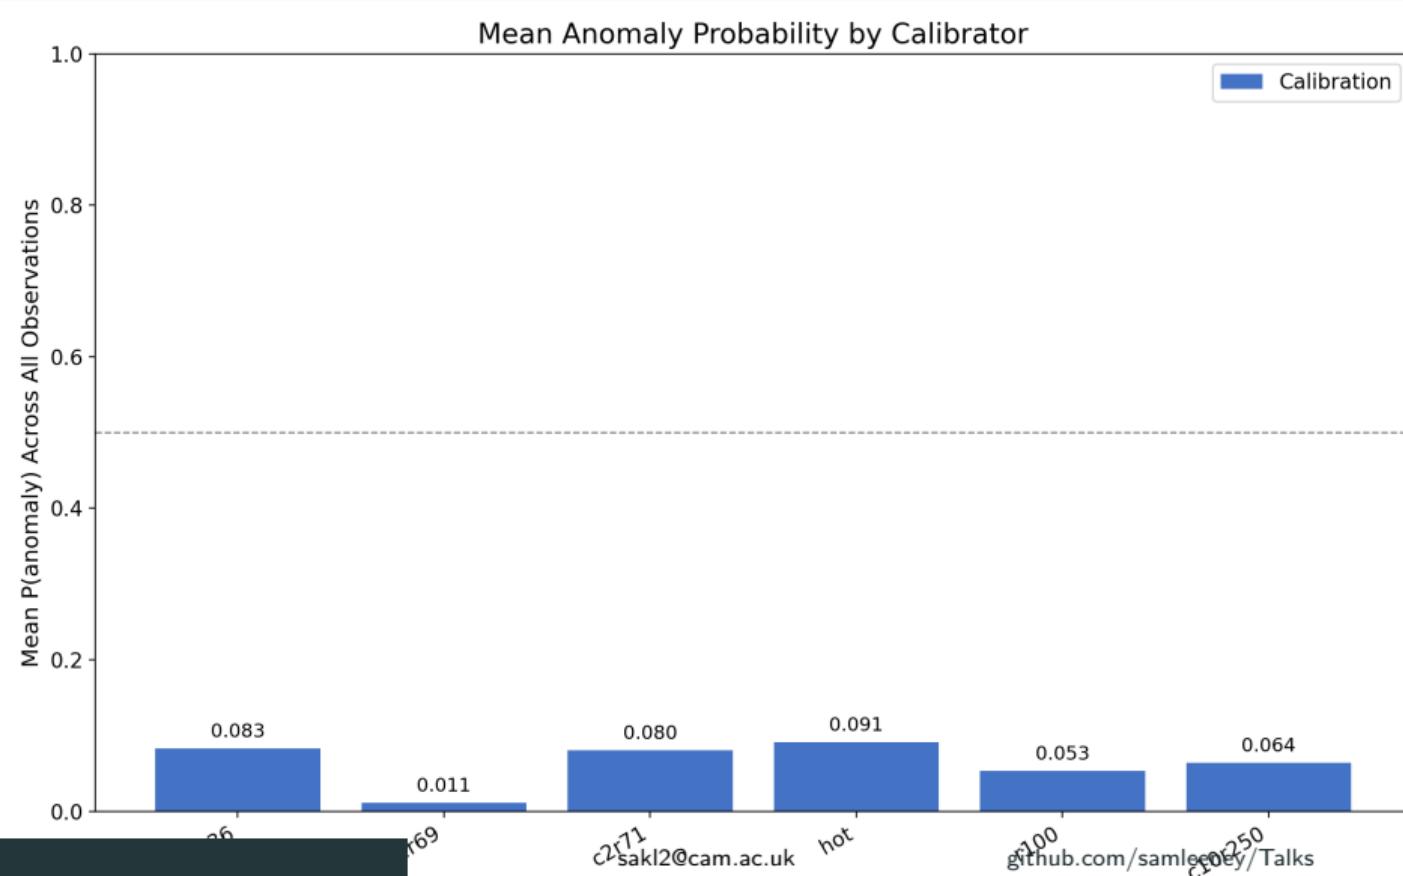

Toy anomaly detection results

- Synthetic linear regression with Gaussian noise plus injected RFI-like anomalies.
- Network jointly fits \hat{y} and spatial $\text{logit}(p)$, achieving perfect 3/3 anomaly recall with zero false positives.
- Posterior $P(\varepsilon = 0|x, y)$ cleanly separates corrupted spectra before calibration.

Modeling system drift from other complex system effects

Modeling environmental features

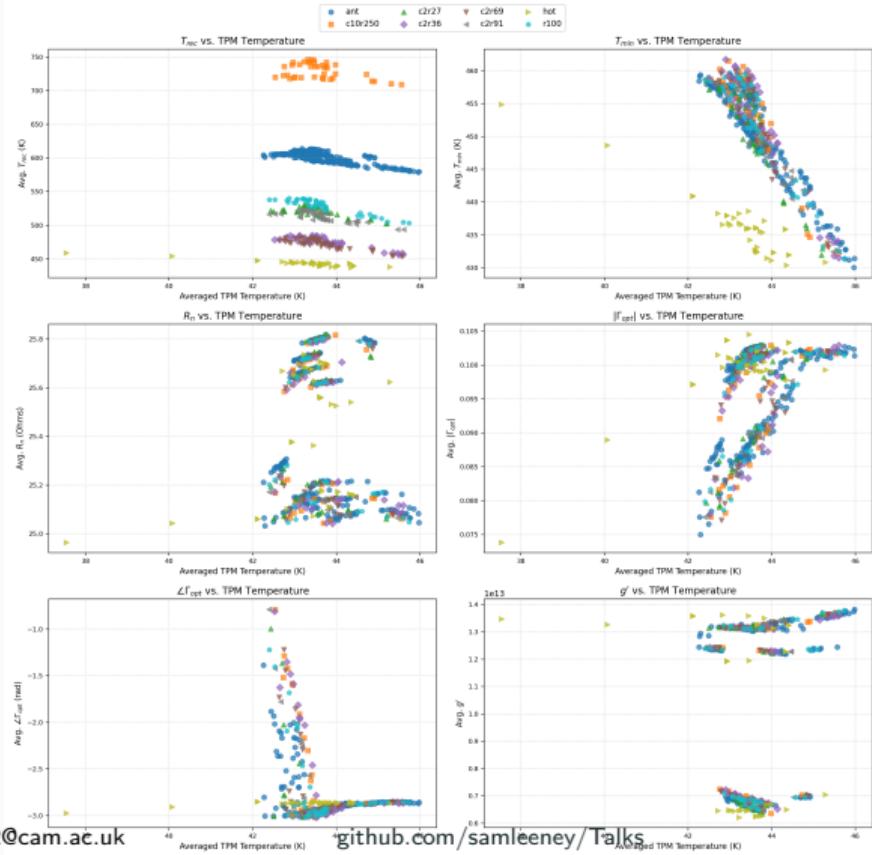

$$\mathcal{L} = \frac{1}{n} \sum_i^n \frac{1}{\mathcal{P}_{src}^{out2}} \left[\mathcal{P}_{src}^{out} - \mathcal{P}_{src}^{pred} \right]^2 \quad \leftarrow \quad \mathcal{P}_{src}^{pred} = gM \left(T_{src}^{in} + \mathcal{T}_{min} + T_0 \frac{4R_N}{Z_0} \frac{|\Gamma_{src} - \Gamma_{opt}|^2}{(1 - |\Gamma_{src}|^2)(1 + |\Gamma_{opt}|^2)} \right)$$

We can train on features that cannot be modeled analytically

Fitting environmental features against fitted noise parameters

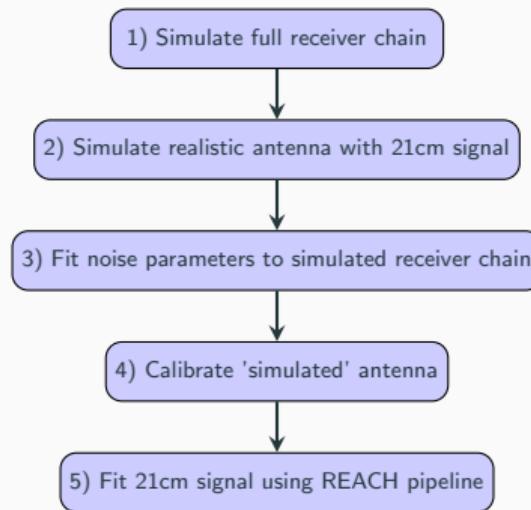

Correlate noise parameters with environmental data

End to end simulations

End to end simulation

We have shown we can calibrate an internal source, we now test the method on as part of the broader system (simulated).

Predicted vs True Antenna Temperature

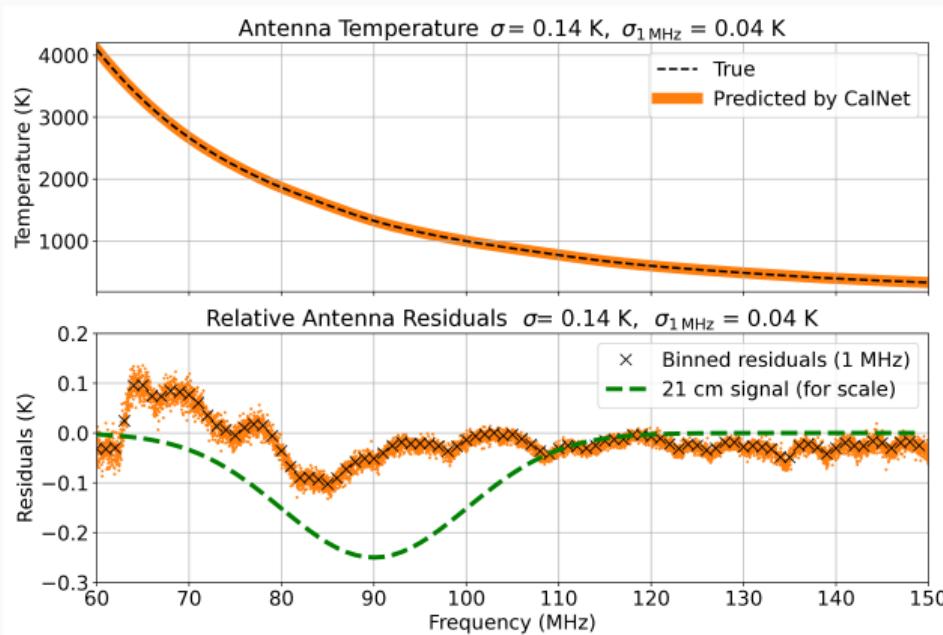

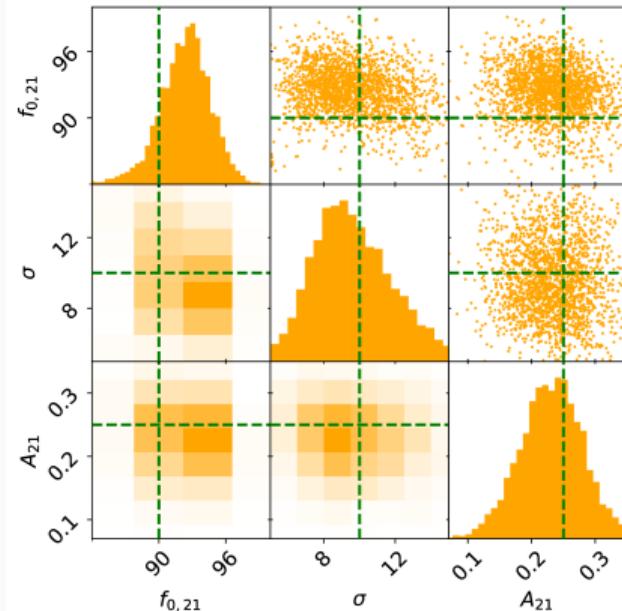

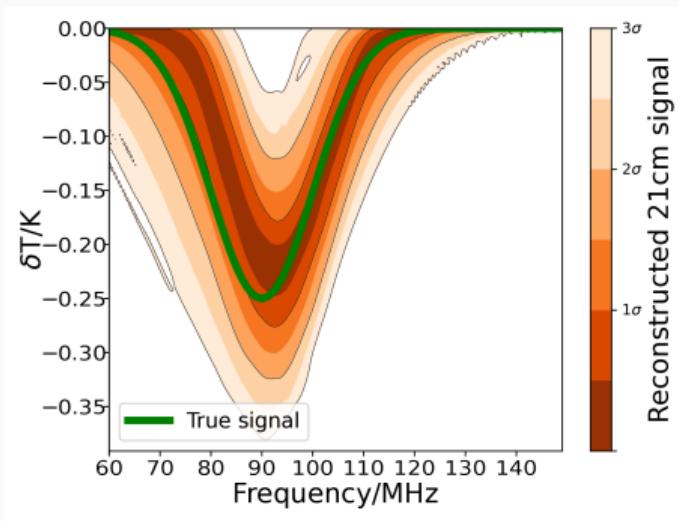

Figure 5: The top panel shows the predicted antenna temperature in orange, with the true temperature overlaid in black dashes

Inferred 21cm Signal

Thank you!

Appendix

Calibration Equation

Typically, substitute in the noise wave parameter equation here (gains cancel)

$$T_{\text{cal}}^* = T_{\text{NS}} \frac{P_{\text{cal}} - P_L}{P_{\text{NS}} - P_L} + T_L \quad (4)$$

Make some matching assumptions and re arrange:

$$\begin{aligned} T_s = & \color{red} T_{\text{NS}} \left(\frac{P_s - P_L}{P_{\text{NS}} - P_L} \right) \frac{|1 - \Gamma_s \Gamma_{\text{rec}}|^2}{1 - |\Gamma_s|^2} + \color{red} T_L \frac{|1 - \Gamma_s \Gamma_{\text{rec}}|^2}{1 - |\Gamma_s|^2} - \color{red} T_{\text{unc}} \frac{|\Gamma_s|^2}{1 - |\Gamma_s|^2} + \\ & - \color{red} T_{\text{cos}} \frac{\Re \left(\frac{\Gamma_s}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) |1 - \Gamma_s \Gamma_{\text{rec}}|^2}{(1 - |\Gamma_s|^2) \sqrt{1 - |\Gamma_{\text{rec}}|^2}} - \color{red} T_{\text{sin}} \frac{\Im \left(\frac{\Gamma_s}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) |1 - \Gamma_s \Gamma_{\text{rec}}|^2}{(1 - |\Gamma_s|^2) \sqrt{1 - |\Gamma_{\text{rec}}|^2}} \end{aligned} \quad (5)$$

Note: We end up with 5 parameters that need to be estimated to calibrate the system.

Calculating the error

By partial derivatives To find the error in T_s , we propagate the errors in Γ_s , Γ_{rec} , P_L , P_{NS} , and P_s :

$$(\Delta T_s)^2 = \left(\frac{\partial T_s}{\partial \Gamma_s} \Delta \Gamma_s \right)^2 + \left(\frac{\partial T_s}{\partial \Gamma_{rec}} \Delta \Gamma_{rec} \right)^2 + \left(\frac{\partial T_s}{\partial P_L} \Delta P_L \right)^2 + \left(\frac{\partial T_s}{\partial P_{NS}} \Delta P_{NS} \right)^2 + \left(\frac{\partial T_s}{\partial P_s} \Delta P_s \right)^2. \quad (10)$$

Calculating the error

$$(\Delta T_s)^2 = \left(\frac{\partial T_s}{\partial \Gamma_s} \Delta \Gamma_s \right)^2 + \left(\frac{\partial T_s}{\partial \Gamma_{rec}} \Delta \Gamma_{rec} \right)^2 + \left(\frac{\partial T_s}{\partial P_L} \Delta P_L \right)^2 + \left(\frac{\partial T_s}{\partial P_{NS}} \Delta P_{NS} \right)^2 + \left(\frac{\partial T_s}{\partial P_s} \Delta P_s \right)^2. \quad (11)$$

$$\frac{\partial T_s}{\partial P_L} = T_{NS} \frac{|1 - \Gamma_s \Gamma_{rec}|^2}{1 - |\Gamma_s|^2} \cdot \frac{P_s - P_{NS}}{(P_{NS} - P_L)^2}, \quad (12)$$

$$\frac{\partial T_s}{\partial P_{NS}} = -T_{NS} \frac{|1 - \Gamma_s \Gamma_{rec}|^2}{1 - |\Gamma_s|^2} \cdot \frac{P_s - P_L}{(P_{NS} - P_L)^2}, \quad (13)$$

$$\frac{\partial T_s}{\partial P_s} = T_{NS} \left(\frac{1}{P_{NS} - P_L} \right) \frac{|1 - \Gamma_s \Gamma_{rec}|^2}{1 - |\Gamma_s|^2}. \quad (14)$$

$$\frac{\partial T_s}{\partial \Gamma_{rec}} = \frac{\partial A}{\partial \Gamma_{rec}} + \frac{\partial B}{\partial \Gamma_{rec}} + \frac{\partial D}{\partial \Gamma_{rec}} + \frac{\partial E}{\partial \Gamma_{rec}}. \quad (15)$$

$$\frac{\partial T_s}{\partial \Gamma_s} = \frac{\partial A}{\partial \Gamma_s} + \frac{\partial B}{\partial \Gamma_s} + \frac{\partial C}{\partial \Gamma_s} + \frac{\partial D}{\partial \Gamma_s} + \frac{\partial E}{\partial \Gamma_s}. \quad (16)$$

$$A = T_{NS} \left(\frac{P_s - P_L}{P_{NS} - P_L} \right) \frac{|1 - \Gamma_s \Gamma_{rec}|^2}{1 - |\Gamma_s|^2}, \quad (17)$$

$$B = T_L \frac{|1 - \Gamma_s \Gamma_{rec}|^2}{1 - |\Gamma_s|^2}, \quad (18)$$

$$C = -T_{unc} \frac{|\Gamma_s|^2}{1 - |\Gamma_s|^2}, \quad (19)$$

$$D = -T_{cos} \frac{\Re \left(\frac{\Gamma_s}{1 - \Gamma_s \Gamma_{rec}} \right) |1 - \Gamma_s \Gamma_{rec}|^2}{(1 - |\Gamma_s|^2) \sqrt{1 - |\Gamma_{rec}|^2}}, \quad (20)$$

$$E = -T_{sin} \frac{\Im \left(\frac{\Gamma_s}{1 - \Gamma_s \Gamma_{rec}} \right) |1 - \Gamma_s \Gamma_{rec}|^2}{(1 - |\Gamma_s|^2) \sqrt{1 - |\Gamma_{rec}|^2}}. \quad (21)$$

Calculating the error

Using $T_{NS} \frac{P_{cal}-P_L}{P_{NS}-P_L} + T_L$

$$(\Delta T_s)^2 = \left(\frac{\partial T_s}{\partial P_s} \Delta P_s \right)^2 + \left(\frac{\partial T_s}{\partial P_L} \Delta P_L \right)^2 + \left(\frac{\partial T_s}{\partial P_{NS}} \Delta P_{NS} \right)^2 \quad (22)$$

$$+ \left(\frac{\partial T_s}{\partial \Gamma_s} \Delta \Gamma_s \right)^2 + \left(\frac{\partial T_s}{\partial \Gamma_{rec}} \Delta \Gamma_{rec} \right)^2. \quad (23)$$

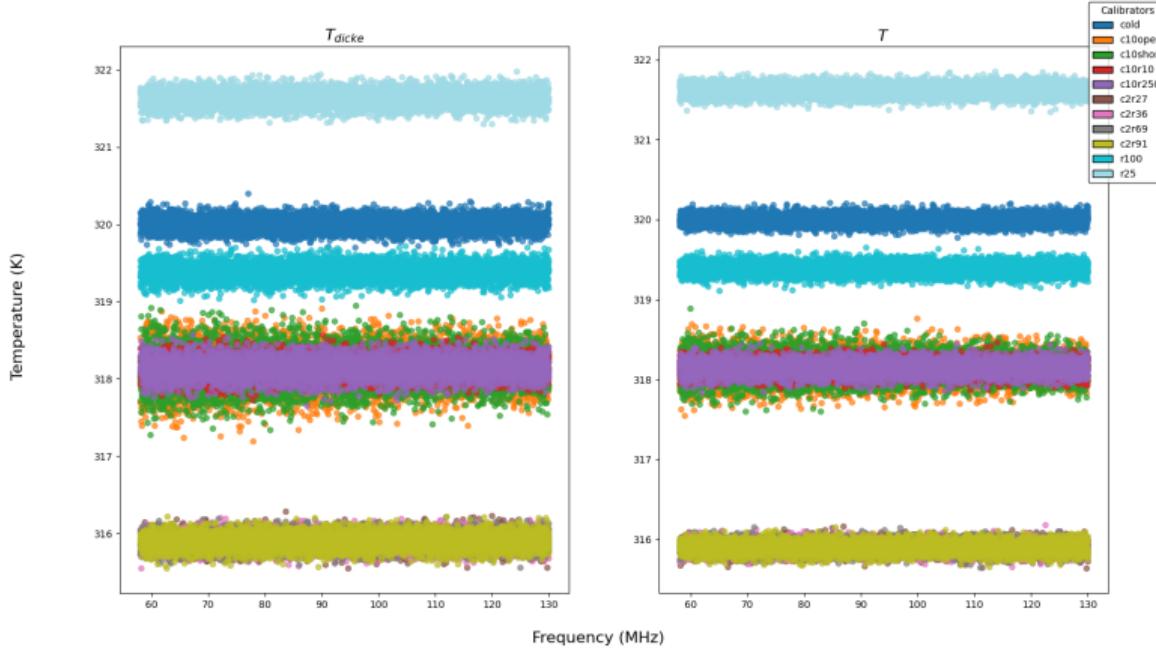

Using noise wave parameters only

$$(\Delta T_s)^2 = \left(\frac{\partial T_s}{\partial P_s} \Delta P_s \right)^2 \quad (24)$$

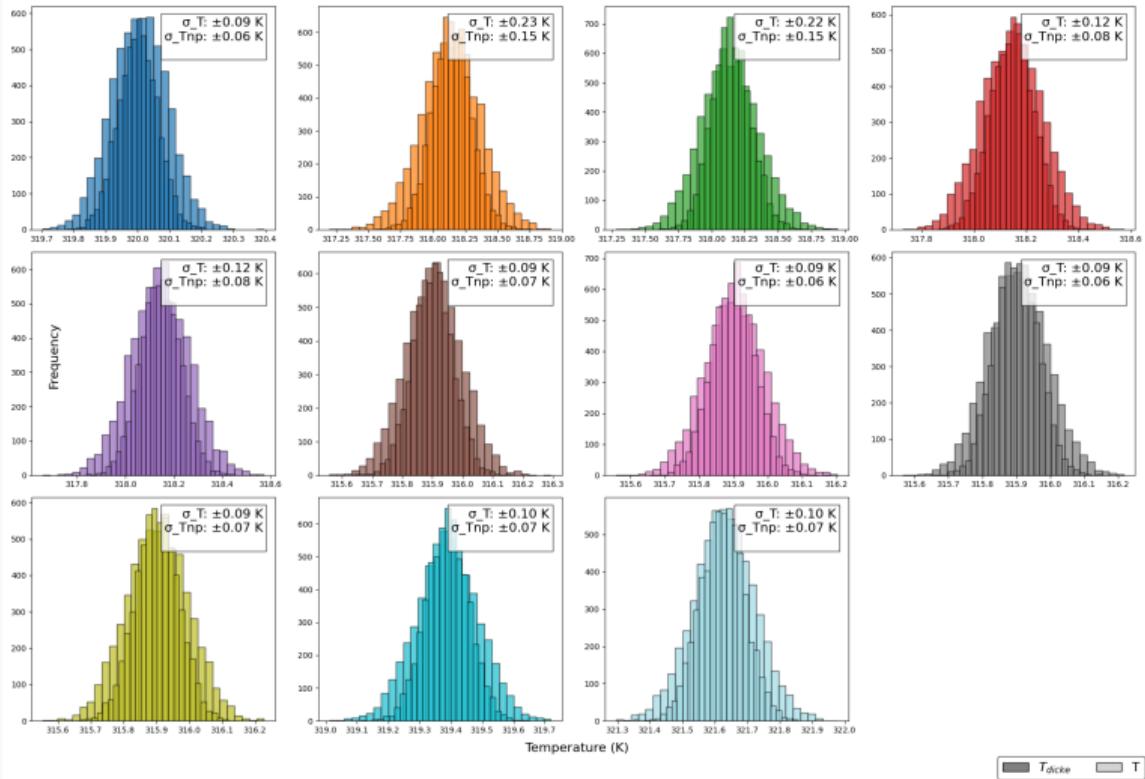

$$+ \left(\frac{\partial T_s}{\partial \Gamma_s} \Delta \Gamma_s \right)^2 + \left(\frac{\partial T_s}{\partial \Gamma_{rec}} \Delta \Gamma_{rec} \right)^2. \quad (25)$$

Note that this argument applies for both noise parameters and noise wave parameters.

There is more
noise when using
 $T_{\text{NS}} \frac{P_{\text{cal}} - P_L}{P_{\text{NS}} - P_L} + T_L$

Combined Histograms of T_{dicke} and T for Each Calibrator

Noise amplified
by **30%** when
using

$$T_{NS} \frac{P_{cal} - P_L}{P_{NS} - P_L} + T_L$$

Why not fit noise (wave) parameters directly?

Noise Parameter Equation:

$$P_{\text{out}}^{\text{src}} = \mathbf{g} M \left(T_{\text{in}}^{\text{src}} + \mathbf{T}_{\text{min}} + T_0 \frac{4R_N}{Z_0} \frac{|\Gamma_{\text{src}} - \Gamma_{\text{opt}}|^2}{(1 - |\Gamma_{\text{src}}|^2)(1 + |\Gamma_{\text{opt}}|^2)} \right) \quad (26)$$

Noise Wave Equation:

$$\begin{aligned} P_{\text{out}}^{\text{src}} = & \mathbf{g} \left[\mathbf{T}_0 + \mathbf{T}_{\text{unc}} |\Gamma_s|^2 \left| \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right|^2 \right. \\ & + T_s (1 - |\Gamma_s|^2) \left| \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right|^2 + \mathbf{T}_{\cos} \Re \left(\Gamma_s \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) \\ & \left. + \mathbf{T}_{\sin} \Im \left(\Gamma_s \frac{\sqrt{1 - |\Gamma_{\text{rec}}|^2}}{1 - \Gamma_s \Gamma_{\text{rec}}} \right) \right] \end{aligned} \quad (27)$$

We still end up with 5 unknowns, as before.

Temporary page!

\LaTeX was unable to guess the total number of pages correctly. As there was some unprocessed data that should have been added to the final page this extra page has been added to receive it.

If you rerun the document (without altering it) this surplus page will go away, because \LaTeX now knows how many pages to expect for this document.
